Prepared for academic project documentation

# CERTIFICATE

This is to certify that the project entitled “**StayNest – Student Accommodation Website**” has been carried out by **Akanksha Singh** as an academic project. The work presented in this report represents the design and development of a student accommodation discovery website created to provide a structured and user-friendly platform for exploring accommodation options.

The project has been completed as part of the academic requirements under appropriate guidance. To the best of our knowledge, the work presented in this report is suitable for academic evaluation.

Project Guide: \_\_\_\_\_

Head of Department: \_\_\_\_\_

Signature: \_\_\_\_\_

Date: \_\_\_\_\_

# DECLARATION

I, **Akanksha Singh**, hereby declare that the project entitled “**StayNest – Student Accommodation Website**” is my original academic work. The project has been developed for educational purposes and the contents presented in this report describe the planning, design and development of the website.

I further declare that the work presented in this report has not been submitted previously to any other institution for the award of a degree, diploma or other academic qualification. Wherever information or concepts from external learning resources have been used, they have been considered as part of the learning and development process.

Student Name: Akanksha Singh

Signature: \_\_\_\_\_

Date: \_\_\_\_\_

# ACKNOWLEDGEMENT

I would like to express my sincere gratitude to my project guide, faculty members and institution for their guidance and support during the development of the StayNest Student Accommodation Website project.

I am thankful for the academic environment and learning opportunities that helped me understand the concepts required to plan and develop a web-based project. The process of creating this website provided practical experience in interface design, web technologies, project organisation and documentation.

I would also like to thank my family, friends and classmates for their encouragement, suggestions and support throughout the project. Their motivation helped me continue working through the different stages of planning, development, testing and documentation.

Finally, I am grateful to everyone who contributed directly or indirectly to the completion of this project.

# ABSTRACT

The **StayNest – Student Accommodation Website** is a web-based platform designed to simplify the process of finding and exploring accommodation for students. Students who move to a new city for education often need to compare different housing options based on location, budget, room type and available facilities. Searching through scattered information can be time-consuming and confusing.

StayNest provides a focused interface where users can begin with a search, browse accommodation listings, apply filtering concepts and open detailed property pages. The project includes sample properties such as Maple House, The Study Loft and Olive Residency to demonstrate how different locations, room types, monthly rents and facilities can be presented in a consistent format.

The website also includes login and registration interfaces and an interested-property interaction that can serve as the foundation for future personalised features. The project is designed with scalability in mind. A future version can connect the front-end to PHP and MySQL to support dynamic property records, user accounts, saved properties, availability and other services.

The project demonstrates the practical application of HTML, CSS, JavaScript, PHP and MySQL concepts in the development of a real-world web solution. The final outcome is a structured student accommodation discovery platform that can be expanded into a complete accommodation management ecosystem.

# TABLE OF CONTENTS

# CHAPTER 1: INTRODUCTION

The StayNest Student Accommodation Website is a web-based project created to simplify the process of discovering suitable accommodation for students. Moving to a new city for education is an important transition, and accommodation is one of the first practical concerns that a student must solve. Students may need to compare locations, room types, monthly rent and facilities while also considering distance from college and everyday convenience.

The project presents a focused digital platform where accommodation information can be organised in one place. Instead of depending on scattered advertisements and unrelated sources, a student can begin with a simple search, browse a collection of properties, use filters and open a detailed property page for further evaluation.

The website has been designed as a foundation for a larger accommodation management system. The current project demonstrates the front-end experience and the structure needed for future database-driven functionality. It includes a home page, property listing interface, property details, search and filtering concepts, login and registration screens and an interested-property interaction.

The purpose of this report is to document the project in a systematic manner. It explains the background of the problem, the objectives, scope, design approach, technologies, system structure, modules, screenshots, testing, limitations and future scope of the StayNest platform.

## CHAPTER 2: BACKGROUND OF THE PROJECT

Students frequently move away from their hometowns for universities, colleges, internships and professional courses. In such situations, finding accommodation can become a time-consuming process. A student may not know the city, the neighbourhoods or the reliable housing options available near the institution.

The accommodation search becomes more difficult when information is distributed across multiple websites, social media posts, advertisements and personal recommendations. Different sources may provide different levels of information, making direct comparison difficult. A student may find a property image in one place, price information in another and facility information somewhere else.

A dedicated student accommodation platform can address this problem by providing a consistent information structure. Every property can be presented using similar categories such as location, rent, room type and facilities. This makes it easier for users to scan options and decide which properties deserve further attention.

StayNest is based on this concept. The project focuses on clarity, visual presentation and a logical user journey. The website is not only a collection of property cards; it is designed as a sequence of discovery, filtering, evaluation and future personalisation.

## CHAPTER 3: PROBLEM STATEMENT

The central problem addressed by the project is the difficulty students face when searching for accommodation in an unfamiliar location. Existing searches may require the user to visit several sources and manually compare information that is presented in different formats.

The first problem is information fragmentation. Property details may not be available in a common structure, and important information may be difficult to locate. The second problem is the lack of efficient filtering. When many properties are available, a student needs a way to reduce results based on location, budget or property type.

The third problem is the gap between a short listing and a final decision. A listing card is useful for browsing, but a student may need a complete detail page before considering an accommodation seriously. The platform therefore needs both a summary view and a detailed view.

StayNest addresses these issues by creating a focused student-oriented experience in which users can discover properties, narrow their options and explore detailed information through a connected website.

## CHAPTER 4: AIM AND OBJECTIVES

The main aim of StayNest is to design and develop a student accommodation discovery platform that makes the process of finding, comparing and evaluating housing options simpler and more organised.

The first objective is to provide a clear home page that communicates the purpose of the website and gives users an immediate starting point for accommodation discovery. The second objective is to display multiple properties in a consistent listing format so that users can scan options efficiently.

The third objective is to provide filtering and search concepts that can reduce irrelevant results. The fourth objective is to create detailed property pages containing information such as property name, location, rent, room type and facilities.

The fifth objective is to establish login and registration interfaces that can support future account-based features. The final objective is to create a scalable foundation that can later be connected to PHP, MySQL and a dynamic database.

## CHAPTER 5: SCOPE OF THE PROJECT

The current scope of the project includes the design and development of the student-facing accommodation discovery experience. The website includes the homepage, navigation, accommodation discovery, property listings, filtering interface, property details and account-related screens.

The scope also includes visual presentation through property images and a responsive layout concept. The project demonstrates how a user can move from a broad search requirement to a specific property page.

A commercial platform would require additional systems such as verified property management, live availability, booking, payment processing, communication, administration and legal compliance. These are outside the core scope of the current academic project but are considered as future enhancements.

The project therefore provides a practical foundation that can grow into a larger platform without changing its basic user journey.

## CHAPTER 6: TARGET USERS

The primary users of StayNest are students searching for accommodation while studying away from home. They may be first-year students, postgraduate students, interns or other learners who require temporary or long-term housing.

Students may have different priorities. Some may focus on monthly rent, some on privacy and room type, and others on facilities such as Wi-Fi, meals, laundry, gym access or air conditioning. The website is therefore designed to present multiple categories of information rather than assuming one universal preference.

Parents and family members are potential secondary users. They may help a student compare options and may value clear property information. In a future version, verified listings and safety-related information could be particularly useful for families.

Property owners and accommodation providers are potential future users of the platform. A provider dashboard could allow authorised users to add listings, update availability and respond to enquiries.

## CHAPTER 7: ONLINE ACCESS AND PROJECT IDENTITY

The StayNest project is available online as a published website. The live website can be accessed at **<https://akrsingh1501-boop.github.io/student-accommodation/>**.

The project repository is identified as **akrsingh1501-boop/student-accommodation**. The repository provides the development location for the project files and supports version-based project management.

The online availability of the project is useful for demonstration because a reviewer can directly observe the website interface. The repository also represents the connection between development work and the published front-end result.

The project identity is built around the StayNest concept: a focused digital environment that helps students explore accommodation options in a more structured way.

## CHAPTER 8: LITERATURE REVIEW AND RELATED CONCEPTS

Property discovery platforms commonly use search, filters, cards and detail pages to help users evaluate options. These patterns are effective because they divide a large information problem into smaller decisions.

Search is generally used for broad discovery. Filtering is used to narrow the result set. Cards are used for quick comparison, while detail pages are used for deeper evaluation. This pattern is particularly suitable for accommodation because users often begin with a broad requirement and gradually become more specific.

Student accommodation has additional requirements compared with general real estate. Students may care about proximity to educational institutions, affordability, room sharing, meals and internet access. A focused platform can therefore present information that is more relevant to the target audience.

The design of StayNest applies these established digital interaction concepts to a student accommodation scenario. The project combines familiar interface patterns with a focused student-centred purpose.

## CHAPTER 9: EXISTING SYSTEM

In a conventional accommodation search, students may use multiple channels. They may browse general property websites, search social media, contact local agents, ask friends or inspect individual advertisements.

The main weakness of this approach is fragmentation. Information may not be presented consistently, and the student may need to manually compare different sources. This can increase the time required to make a decision.

Another limitation is that general property platforms may contain a large amount of information that is not specifically relevant to students. A student may need to search through many properties that do not match their budget, room type or educational location.

These observations create a need for a more focused and structured student accommodation discovery experience.

## CHAPTER 10: PROPOSED SYSTEM

The proposed StayNest system provides a single student-focused interface for accommodation discovery. The user begins at the homepage and can search or browse properties based on personal requirements.

The listing page presents multiple accommodation options in a consistent card format. Filters help narrow the results. A selected property can then be opened in a detailed view where the user can review additional information.

The account interface provides the foundation for future personalisation. An interested-property feature can eventually be connected to a database so that each user can maintain a personal list of accommodation options.

The proposed system is modular. New features such as reviews, maps, booking, notifications and provider dashboards can be added later without removing the core discovery workflow.

# CHAPTER 11: FEASIBILITY STUDY

Technical feasibility considers whether the project can be developed using available technologies and tools. StayNest uses common web technologies and can be developed using a standard computer and development environment.

Operational feasibility considers whether users can understand and use the proposed system. The project uses familiar interaction patterns such as search, cards, buttons, filters and detail pages, making the basic workflow easy to understand.

Economic feasibility is also favourable for an academic prototype because the core development tools and technologies are widely available. A larger commercial system would introduce hosting, maintenance and service costs, but the prototype can be developed with relatively accessible resources.

Schedule feasibility considers whether the project can be divided into manageable stages. The project can be developed through interface design, page creation, image integration, interaction development and future backend integration.

## CHAPTER 12: SYSTEM REQUIREMENTS

The project can be developed using a standard personal computer with a modern web browser. A basic development environment is sufficient for creating the front-end interface and testing the website.

Software requirements include a code editor such as Visual Studio Code, a modern web browser, HTML and CSS support, JavaScript support and, for backend development, PHP and MySQL. GitHub can be used for source code management and front-end publication.

Hardware requirements for a prototype are modest. A computer with sufficient memory for a code editor, browser and local development tools is adequate. An internet connection is useful for repository management and online deployment.

The system requirements can be expanded if the project develops into a larger platform with a database server, administration tools and additional services.

## CHAPTER 13: TECHNOLOGIES USED

HTML is used to create the structure of the web pages. It defines headings, sections, forms, buttons, links, images and other elements that make up the interface.

CSS is used to control visual presentation. It manages spacing, typography, layouts, cards, responsive behaviour and the overall visual appearance of the website.

JavaScript can be used to provide client-side interaction. Examples include filtering, handling button actions, updating the interface and communicating with backend services through requests.

PHP provides a suitable server-side foundation for dynamic features. It can process registration, login, property retrieval and user interactions. MySQL can store users, properties and relationships between users and interested properties.

GitHub supports repository management and online publication of the front-end project. The combination of these technologies provides a practical foundation for a full-stack accommodation platform.

## CHAPTER 14: SYSTEM ARCHITECTURE

The StayNest architecture can be understood as a layered system. The presentation layer contains the pages and interface elements visible to the user. The interaction layer manages actions such as search, filtering and interested-property responses. The application layer can process requests using PHP. The data layer can store users, properties and related information in MySQL.

The user interacts with the presentation layer through a browser. A search or filter action can be processed by JavaScript and, in a dynamic version, sent to a PHP endpoint. PHP can then communicate with the database and return matching information.

This layered structure supports maintainability. Changes to the visual interface can be made without redesigning the database, while changes to data storage can be managed without completely rebuilding the user experience.

The architecture also supports future expansion to mobile applications or other client interfaces that communicate with the same backend services.

## CHAPTER 15: DATABASE DESIGN

A dynamic accommodation platform requires structured data. A Users table can store account information such as user identity, email and securely stored password data. A Properties table can store property name, location, rent, room type, description, images and availability.

An Amenities structure can represent facilities available at properties. Depending on the design, amenities can be stored as fields or as related records. A UserInterestedProperties table can connect users with the properties they have marked for future consideration.

A database structure makes it possible to retrieve properties based on filters. For example, a query can return properties in a selected location with rent below a selected maximum value.

A production database would also require validation, indexes, access control and careful handling of personal data.

## CHAPTER 16: ER MODEL CONCEPT

The core entities of the proposed system are User, Property, Amenity and Interested Property. A user can be associated with many interested properties, and a property can be marked as interesting by many users.

The relationship between User and Property is therefore many-to-many when interested properties are considered. This relationship can be implemented through an intermediate table containing user and property identifiers.

A property can also be associated with multiple amenities. This allows the system to represent facilities in a structured manner and makes future filtering easier.

The entity relationship concept provides a logical foundation for future database implementation and ensures that the system can grow beyond hard-coded sample data.

## CHAPTER 17: USER FLOW AND WORKFLOW

The main user journey begins when a visitor opens the StayNest homepage. The user learns the purpose of the website and can begin searching for accommodation.

The next stage is discovery. The user can view properties and use available filters to reduce the number of results. A property that appears suitable can be opened for detailed evaluation.

After reviewing the details, the user may mark the property as interested or continue comparing other options. In a future version, the user could request a visit, send an enquiry or begin a booking process.

The workflow is intentionally progressive. Users first receive a broad overview and then access more detailed information only when they choose a specific property.

## CHAPTER 18: HOME PAGE MODULE

The home page is the first major interface of the website. Its primary responsibility is to communicate what StayNest offers and provide a clear starting point for accommodation discovery.

The page uses a strong visual introduction, a search area and featured property content. The arrangement allows a visitor to understand the purpose of the platform quickly.

The home page also establishes the visual identity of the project. Typography, imagery, buttons and spacing work together to create a consistent first impression.

A future version can personalise the homepage based on the user's city, college or previous searches.

Figure 1: StayNest home page screenshot.

# CHAPTER 19: PROPERTY LISTING MODULE

The property listing page is the central browsing interface. It displays multiple accommodation options in a consistent format so that users can scan them efficiently.

Each property card can contain an image, name, location, monthly rent, room type and selected amenities. The card is deliberately a summary rather than a complete description.

The View Details action allows the user to move from quick comparison to deeper evaluation. The Interested action creates a path toward future personalised activity.

The listing module can later be connected to database results so that the number and content of cards change dynamically according to search conditions.

Figure 3: Property listing interface.

## CHAPTER 20: SEARCH AND FILTER MODULE

Search helps users begin with a broad requirement such as a city, neighbourhood or educational institution. Filtering then allows the user to refine the result set.

Possible filter categories include location, property type and price range. Additional categories can include room sharing, facilities, furnished status and distance from a college.

Filtering improves usability because users do not need to inspect every property. It also creates a more personalised discovery experience.

In a backend implementation, filter values can be converted into database conditions and the system can return only matching properties.

Figure 4: Search and filter interface.

## CHAPTER 21: PROPERTY DETAILS MODULE

The property details page provides a deeper view of one accommodation option. It is intended for users who have already identified a property that appears relevant.

The page can include the property name, location, monthly rent, room type, description, facilities and visual information. Additional details can include availability, deposit, policies and contact options.

A consistent detail-page structure helps users compare properties even when they are viewing them at different times. It also creates a professional and predictable experience.

The detail page is one of the most important decision-making screens because it connects discovery with possible future action.

## CHAPTER 22: MAPLE HOUSE CASE STUDY

Maple House is presented as a private-room student accommodation example in North Campus, Delhi. The property demonstrates how a listing can communicate a location, room type, monthly rent and facilities.

The example is useful because it shows how a student can quickly understand the basic accommodation offer and then open a more detailed view when required.

In a dynamic platform, Maple House could be represented as a database record. Its availability, images, description and facilities could be updated without changing the structure of the website.

The case study demonstrates the value of consistent property information.

The screenshot displays the StayNest website interface for the Maple House property. The top navigation bar includes links for Home, Find a Stay, About, List Your Property, and an Account dropdown. The breadcrumb trail shows Home > Find a Stay > Maple House. The property name 'Maple House' is accompanied by a 'Verified' badge and a location pin indicating 'North Campus, Delhi'. A large main image shows a private room with a bed, desk, and wardrobe. To the right, the price is listed as ₹14,500 / month, with 'All inclusive' details. Below the price, there are icons for Private rooms, Wi-Fi, and Meals. A 'Move-in date' section with a 'Select date' input and a calendar icon is present. Two buttons, 'I'm Interested' and 'Schedule a Visit', are provided. The 'About this property' section describes the accommodation as comfortable private rooms for students with essential amenities. The 'Amenities' section lists Wi-Fi, Meals, Laundry, 24/7 Security, Power Backup, and Housekeeping. The 'Property Details' table lists the Property Type as Student Residence, Room Type as Private Rooms, Bathrooms as Attached, Security Deposit as ₹10,000, and Notice Period as 30 Days. The 'Location' section shows the address 'North Campus, Delhi' and a map.

| Property Details |                   |
|------------------|-------------------|
| Property Type    | Student Residence |
| Room Type        | Private Rooms     |
| Bathrooms        | Attached          |
| Security Deposit | ₹10,000           |
| Notice Period    | 30 Days           |

Figure 5: Maple House property details.

## CHAPTER 23: THE STUDY LOFT CASE STUDY

The Study Loft is presented as a shared-room student accommodation example in Koramangala, Bengaluru. It demonstrates a different accommodation model from a private-room residence.

The example includes facilities such as Wi-Fi, gym access and meals. This shows how a property can be evaluated not only by rent and location but also by the lifestyle facilities it provides.

The detail structure allows users to compare The Study Loft with other properties using common categories. Future data could include sharing capacity, availability and resident reviews.

This case study demonstrates why a student accommodation platform should support different types of housing rather than a single property model.

The screenshot displays the 'The Study Loft' property listing on the StayNest website. The header includes navigation links: Home, Find a Stay, About, and List Your Property, along with a user account icon. The breadcrumb trail shows 'Home > Find a Stay > The Study Loft'. The property title 'The Study Loft' is marked as 'Verified' and located in 'Koramangala, Bengaluru'. A large image shows a modern shared room with two beds, a desk, and a window view of the city. To the right, the price is listed as ₹12,000 / month, all inclusive. Amenities include Shared rooms, Wi-Fi, Gym, and Meals. A 'Move-in date' section allows users to select a date or click 'I'm Interested' or 'Schedule a Visit'. The 'Property Details' section lists: Property Type (Student Residence), Room Type (Shared Rooms), Bathrooms (Common), Security Deposit (₹8,000), and Notice Period (30 Days). The 'Location' section shows a map of Koramangala, Bengaluru, with a red pin indicating the property location. Below the main image, there are smaller images of other property areas and a '+10 Photos' button. The 'About this property' section describes the vibrant community atmosphere and convenient location. The 'Amenities' section lists: Wi-Fi, Gym, Meals, Study Area, Laundry, 24/7 Security, and Power Backup.

Figure 6: The Study Loft property details.

## CHAPTER 24: OLIVE RESIDENCY CASE STUDY

Olive Residency is presented as a private-room student accommodation example in Viman Nagar, Pune. It demonstrates how location, room type, rent and facilities can be combined in a single property presentation.

Facilities such as air conditioning, laundry and meals can influence a student's decision. Different students may value different facilities, so structured information supports individual comparison.

A future version could include a map, availability status, reviews and a direct enquiry function for the property.

The example reinforces the importance of presenting accommodation information in a consistent format.

The screenshot displays the 'Olive Residency' listing on the StayNest platform. The header includes the StayNest logo and navigation links: Home, Find a Stay, About, List Your Property, and an Account dropdown. The breadcrumb trail shows 'Home > Find a Stay > Olive Residency'. The property name 'Olive Residency' is accompanied by a 'Verified' badge and a location pin for 'Viman Nagar, Pune'. There are 'Share' and 'Save' buttons. A large image shows a modern bedroom with a bed, wardrobe, and desk. To the right, the price is listed as '₹16,000 / month' with 'All inclusive' amenities: Private rooms, AC, Laundry, and Meals. A 'Move-in date' selector is present, along with 'I'm Interested' and 'Schedule a Visit' buttons. Below the main image is a gallery of smaller photos and a '+9 Photos' button. The 'About this property' section describes it as premium private rooms near the airport and IT parks. The 'Amenities' section lists Wi-Fi, AC, Laundry, Meals, Housekeeping, 24/7 Security, and Power Backup. The 'Property Details' table lists: Property Type (Student Residence), Room Type (Private Rooms), Bathrooms (Attached), Security Deposit (₹12,000), and Notice Period (30 Days). The 'Location' section shows a map of Viman Nagar, Pune, with nearby landmarks like Phoenix Marketplace and Symbiosis International University.

## CHAPTER 25: LOGIN MODULE

The login page provides an entry point for returning users. While public browsing can remain available, account access becomes important when the platform needs to remember user activity.

A logged-in user could save properties, maintain an interested list, receive recommendations and manage enquiries. The login module therefore supports the transition from a general browsing website to a personalised platform.

A complete implementation should use secure password hashing, session management, validation and appropriate error handling.

The current interface provides the visual foundation for these future capabilities.

Figure 8: Login page.

## CHAPTER 26: REGISTRATION MODULE

The registration page allows a new user to create an account. The registration process should remain simple and should request only the information required for the initial account.

Future account preferences could include preferred city, college, maximum budget and room type. These preferences could be used to improve recommendations.

A production registration process should include input validation, secure password storage and, where required, email verification.

The registration module establishes the foundation for a user database and personalised features.

The image shows a mobile application interface for a registration page. At the top, there is a status bar with the time 14:43, a location icon, and various system icons. Below the status bar is a browser-like address bar showing a close button (X), a lock icon, the URL 'akrsingh1501-boop.github.io', and a share icon. The main content area is a white card with a light gray border and a subtle shadow. The card has a title 'Register' in bold black text. Below the title are four text input fields with placeholder text: 'Enter your name', 'Enter your email', 'Create password', and 'Confirm password'. Below these fields is a blue button with the text 'Register'. At the bottom of the card, there is a link that says 'Already have an account? [Login here](#)'. Below the card is a navigation bar with a search icon and the text 'Search...', a play button icon, a menu icon (three horizontal lines), and a home icon. At the very bottom is an Android-style navigation bar with back, home, and recents icons.

Figure 9: Registration page.

## CHAPTER 27: INTERESTED PROPERTY FEATURE

Accommodation search is often a comparison process. A student may find several properties that appear suitable and may want to remember them while continuing to browse.

The Interested action provides a simple way to mark a property for further consideration. Immediate feedback helps the user understand that the action has been recognised.

In a dynamic version, the action can create a relationship between the logged-in user and the selected property. The user can then access a personal list of interested properties.

This feature can later support recommendation systems and saved searches.

## CHAPTER 28: USER INTERFACE DESIGN

The interface uses familiar web design patterns such as cards, buttons, headings, search areas and structured sections. These patterns reduce the effort required to understand the website.

The listing page uses a lower information density suitable for browsing, while the detail page uses a higher information density suitable for evaluation.

Consistent spacing, typography, images and buttons create a unified visual language. Reusable patterns also make future development easier.

The interface can continue to improve through user testing, responsive testing and accessibility evaluation.

## CHAPTER 29: RESPONSIVE DESIGN

Students may use the website on laptops, tablets and mobile phones. Responsive design allows the layout to adapt to different screen widths.

A responsive interface may change the number of cards per row, stack content vertically and adjust navigation for smaller screens.

Images should remain properly sized, text should remain readable and important actions should remain easy to tap.

Responsive testing is therefore an important part of the development and quality assurance process.

## CHAPTER 30: ACCESSIBILITY AND USABILITY

Accessibility improves the experience for users with different abilities and different methods of interacting with a website. Clear headings, readable text, meaningful labels and logical navigation are important foundations.

Images should have suitable alternative text when they convey important information. Forms should clearly communicate required fields and errors.

Usability is closely connected to clarity. A user should understand what a button does and where an action will lead.

Future development can include keyboard testing, screen-reader checks and contrast evaluation.

## CHAPTER 31: FRONT-END IMPLEMENTATION

The front-end consists of page structure, styling and interaction. HTML defines the content and semantic structure, CSS provides the visual design, and JavaScript can manage dynamic behaviour.

Reusable property card patterns reduce repetition and make it easier to add new properties. Images are organised as assets so that they can be updated independently from the page structure.

A clear file organisation strategy helps development and troubleshooting. Pages, styles, scripts and images should have predictable locations and names.

As the project grows, reusable components and templates can improve consistency and development speed.

## CHAPTER 32: BACK-END IMPLEMENTATION PLAN

A future dynamic version can connect the front-end to PHP endpoints and a MySQL database. Registration data can be stored securely, properties can be retrieved dynamically and user actions can be associated with accounts.

PHP can receive requests, validate inputs, interact with the database and return responses. JavaScript can update the interface based on the response.

This approach can transform the current prototype into a live accommodation management system with continuously updated information.

The backend should be designed with validation, secure queries, authentication and access control from the beginning.

## CHAPTER 33: TESTING STRATEGY

Testing is used to confirm that the website works as expected. Functional testing checks whether actions and links behave correctly. Visual testing checks layout, images, typography and spacing.

Responsive testing checks the website on different screen sizes. Form testing checks valid and invalid inputs. Navigation testing checks that users can move between major sections without confusion.

Testing should be repeated after major changes because a change in one file can affect another page or feature.

A written test checklist improves consistency and helps identify issues before project submission.

## CHAPTER 34: TEST CASES

A homepage test checks whether the page loads, displays its major sections and provides a clear route toward accommodation discovery.

A listing test checks whether property cards appear correctly, images match their properties and the View Details action opens the expected information.

A filter test checks whether selected criteria produce the expected change in the visible result set. An interested-property test checks whether the user receives appropriate feedback.

Login and registration tests check whether the forms are visible, fields are understandable and navigation between account pages works correctly.

## CHAPTER 35: SECURITY AND PRIVACY

If StayNest becomes a full platform, security and privacy will be essential. User accounts may contain personal information and the system may process enquiries and accommodation-related activity.

Passwords should be stored using secure hashing rather than plain text. Input should be validated and database queries should be protected from injection attacks.

Access control should restrict administrative functionality. Privacy information should explain what data is collected, how it is used and how it is protected.

Security should be treated as a continuous part of development rather than a feature added at the end.

## CHAPTER 36: ADVANTAGES

The main advantage of StayNest is its focused purpose. The platform is designed specifically around student accommodation rather than general property browsing.

The card-based listing supports quick comparison. Search and filters can reduce irrelevant results. Detail pages provide deeper information, and account screens create a foundation for personalised features.

The project is scalable because sample properties can later be replaced with database records. New properties and features can be added without changing the basic user journey.

The project also provides practical experience with interface design, web development, image management, user interaction and full-stack planning.

## CHAPTER 37: LIMITATIONS

The current project is an academic prototype and demonstration of a student accommodation platform. A production service would require additional systems for verified information, availability and management.

Sample property information would need to be connected to reliable real-world data for a commercial platform. A complete booking system would require payments, availability management, cancellation rules and communication workflows.

The current project can be improved by connecting the front-end to a backend and database so that properties and user activity are managed dynamically.

These limitations identify opportunities for future development.

## CHAPTER 38: FUTURE SCOPE

StayNest has significant potential for future expansion. A live availability system could show whether rooms are available for a selected move-in date.

Map-based search could show properties in relation to colleges, public transport and important locations. Reviews and ratings could help students learn from previous residents.

Other features could include visit scheduling, owner dashboards, notifications, saved searches, personalised recommendations, chat support and mobile applications.

An administrator dashboard could manage users, properties, verification requests and reports. With continued development, StayNest could become a complete ecosystem connecting students with accommodation providers.

## CHAPTER 39: CONCLUSION

The StayNest Student Accommodation Website demonstrates how a focused web platform can address a practical problem faced by students. Finding accommodation in a new city can be confusing and time-consuming when information is spread across different sources.

The project connects the major stages of the discovery journey. The homepage introduces the purpose, search and filtering support discovery, property cards enable comparison and detail pages provide deeper information.

The sample properties demonstrate how different locations, room types, rents and facilities can be represented in a consistent format. Login and registration screens provide a foundation for future personalised functionality.

From a technical perspective, the project provides a foundation for HTML, CSS, JavaScript, PHP and MySQL development. With further work, it can become a dynamic platform supporting students, families, property owners and administrators.

## CHAPTER 40: REFERENCES AND PROJECT LINKS

The primary project reference is the live StayNest website: **<https://akrsingh1501-boop.github.io/student-accommodation/>**.

The project repository reference is: **[akrsingh1501-boop/student-accommodation](https://github.com/akrsingh1501-boop/student-accommodation)**.

Additional development references include standard documentation and learning resources related to HTML, CSS, JavaScript, PHP, MySQL, responsive web design and GitHub-based project management.

The screenshots included in this report document the major interfaces of the project, including the homepage, property listing, filtering interface, property detail pages, login page, registration page and navigation interface.

## APPENDIX A: SAMPLE PROPERTY COMPARISON

The following table summarises the sample properties used in the project. A structured comparison makes it easier to understand how a future platform can present accommodation options using common fields.

| Property        | Location               | Room Type | Monthly Rent | Facilities         |
|-----------------|------------------------|-----------|--------------|--------------------|
| Maple House     | North Campus, Delhi    | Private   | ■14,500      | Wi-Fi, Meals       |
| The Study Loft  | Koramangala, Bengaluru | Shared    | ■12,000      | Wi-Fi, Gym, Meals  |
| Olive Residency | Viman Nagar, Pune      | Private   | ■16,000      | AC, Laundry, Meals |

The sample properties demonstrate the value of a consistent data structure. Although the properties differ in location, room type, rent and facilities, users can still compare them because the information is organised into similar categories. A future comparison tool could allow users to select several properties and view them side by side.

## APPENDIX B: PROJECT SCREENSHOTS

The following screenshots document the major interfaces of the StayNest website. They are included as visual evidence of the project design and user experience.

Appendix Figure: Home page interface.

Appendix Figure: Navigation and responsive interface.

Appendix Figure: Property listing page.

Appendix Figure: Search and filter interface.

Appendix Figure: Maple House property details.
